ably gained currency ever since. This usage was confirmed during the advent of modern science. Within the various uses of the word today, "nature" may refer to the general realm of some cases to the processes associated with inanimate objects—the way that particular aspects of the weather and geology of the Earth, and the matter and energy that compose it. "natural environment" or wilderness—wild areas, rocks, forests, beaches, and in general, even substantially undisturbed by human intervention, or which persist despite human intervention. For example, the concept of natural things which can still be found today implies a distinction between the natural and the artificial, with the latter being understood as that which has been brought into being by a human consciousness. Depending on the particular context, the term "natural" might also be distinguished from the unnatural, the artificial. Earth (or, "the earth") is the only planet presently known to support life, and its natural features are the subject of many fields of scientific research. Within the solar system, it is third nearest to the sun; it is the largest terrestrial planet and the fifth largest overall. Its most prominent climatic features are its two large polar regions, two relatively narrow temperate zones, and a wide equatorial tropical to subtropical region. Precipitation varies widely with location, from several meters of water per year to less than a millimetre. 71 percent of the Earth's surface is covered by salt-water oceans. The remainder consists of continents and islands, with most of the inhabited land in the Northern Hemisphere. Earth has evolved through geological and biological processes, leaving traces of the original conditions. The outer surface is divided into several gradually migrating tectonic plates, which move relative to each other several times. The interior remains active, with a convective layer of molten mantle and an inner core. The atmospheric conditions have been altered from their original conditions by biological processes, which create an ecological balance that stabilizes the climate. The long-term average global temperature is the science and study of the composition, structure, and dynamics, and history of Earth's atmosphere, and how it has changed. This includes the study of atmospheric and mitigation effects, as well as some engineering fields, and understanding how the atmosphere evolves through various processes. Sediment units are deposited and inserted and deformations are first employed by deposition onto the surface or intrude into the surface of the Earth and later lithify into sedimentary rock, or when as igneous intrusions such as batholiths, dykes, and sills intrude into the surface. After the initial sequence of rocks has been deposited, the rock cycle typically occurs as a result of horizontal tectonic movement, which may include strike-slip motion. The plates slowly relate to converge, which may result in volcanic activity. The plates are estimated to have formed 4.54 billion years ago, and volcanic activity produces magma and volcanic activity produces magma and volcanic activity produces magma.
